Acute Coronary Syndromes in young: In whom? Why?

Evangelos Pissimissis MD, FESC

Director of 2nd Cardiology Dpt.
Tzaneio Gen. Hospital, Pireaus

Jan. 15, 2014
Prevalence of Coronary Heart Disease by Age and Sex in the U.S. from 1999-2004

BACKGROUND

• Acute coronary syndrome (ACS) is rarely encountered in young adults and may have unusual causes [Thrombophilia, Kawasaki]

• Data on incidence, risk factors and clinical outcome of ACS in this particular subset are limited.

• On currently available evidence, young patients represent 0.4% - 19% of all ACS cases, depending on the cut-off age used (<45-35-30 years)
197 men, 187 women
- coronary risk factors measured 3 times (mean age 15, 27, 33.)
- Electron beam computed tomography for CAC.

Coronary artery calcification 31% in men and 19% in women

CASS Study: Seven-year survival curve of younger versus older men after MI. [84% vs 75%]
CASS Registry: Seven-year survival curve of younger versus older women [90% vs 77%]
The causes for MI among patients aged less than 45 can be divided into four groups:

- Atheromatous CHD
- Non-atheromatous CHD
- Hypercoagulable states
- MI related to substance misuse
Survival in 100 pts < 30 years with ACS

Myocardial Infarction in Patients younger than 30 years, Puricel et al.
I. Atherosclerotic CAD

• The atheromatous process starts in early childhood. In a necropsy study of 760 young adult patients who died of various causes, advanced CHD was found in 20% of men and 8% of women aged 30-34 yrs.

• The pathological determinants of atherosclerosis in youth (PDAY) study and Bogalusa heart study also reflect similar trends.
ASSOCIATION BETWEEN MULTIPLE CARDIOVASCULAR RISK FACTORS AND ATHEROSCLEROSIS IN CHILDREN AND YOUNG ADULTS for the Bogalusa Heart Study

The NEW ENGLAND JOURNAL of MEDICINE

Figure 1. The Prevalence of Fibrous-Plaque Lesions in the Aorta and Coronary Arteries in 204 Children and Young Adults, According to Age.
There is a consistent trend toward a greater prevalence of coronary-artery lesions with increasing age (P = 0.001).

Autopsies on 204 young persons 2 to 39 years of age, who had died from various causes, principally trauma

ASSOCIATION BETWEEN MULTIPLE CARDIOVASCULAR RISK FACTORS ANDATHEROSCLEROSIS IN CHILDREN AND YOUNG ADULTS

for the Bogalusa Heart Study

Figure 3. The Effect of Multiple Risk Factors on the Extent of Atherosclerosis in the Aorta and Coronary Arteries in Children and Young Adults.

Values shown are the percentages of the intimal surface covered with lesions in subjects with 0, 1, 2, and 3 or 4 risk factors. Risk factors were elevated values for body-mass index, systolic blood pressure, and serum triglyceride and LDL cholesterol concentrations, defined as values above the 75th percentile for the study group (specific for study period, race, sex, and age). There were 52 subjects with no risk factors, 20 with one, 14 with two, and 7 with three or four. The P value is based on the analysis of trend. A marked increase in the percentage of the intimal surface covered by fibrous plaques is evident in the coronary vessels of subjects with multiple risk factors.

Autopsies on 204 young persons 2 to 39 years of age, who had died from various causes, principally trauma.

I. ATEROMATOUS CAD

Angiographic findings

• Significantly differed in patients <45 years.
• Increased prevalence of normal coronary arteries (up to 18%) and minor coronary abnormalities in the CASS study.
• Single vessel disease was found in 38% of subjects.
CASS Registry: Seven-year survival curve of patients with zero-vessel disease (normal coronary arteries and nonobstructive narrowing) versus those with obstructive coronary disease.
I. ATHEROMATOUS CAD
Smoking

- The aetiology of atheromatous CHD was linked to the conventional risk factors as in adults. Among young patients with reported atheromatous process, cigarette smoking was found in up to 92%.

- In a study of patients who had PCI, the prevalence of smoking was found to be higher in patients < 40 years as compared with patients over 60 years (58.7% and 43%, p<0.01).
Why Target Youth?

80% of adult smokers started smoking before they finished high school

Prevalence and Risk Factors for Initiation of Smoking in Greek High-School Students

Lazaros T. Sichletidis *, Diamantis A. Chloros, Anastasios I. Tsiotsios and Dionisios G. Spyratos

Abstract: The smoking habits of 9,276 high-school students (15-18 years old) in six cities of Northern Greece were studied using a questionnaire in order to determine the prevalence and possible risk factors for initiation of smoking. We observed that 29.6% of high-school students (32.6% of boys and 26.7% of girls) were current smokers. A percentage of 43.3% had started smoking before the age of 14. Reactive behaviour towards parents’ and teachers’ advice (40.2%) and the existence of smoking friends (40.1%) were the main reasons of initiation. A well-planned integrated anti-smoking campaign is urgently required, especially among students and teachers.
I. ATHEROMATOUS CAD

Family History of CAD

- In a study done in London among young patients with MI, positive family history of premature CHD was found in 39%.

- The children born of parents with premature CHD have more lipid abnormalities, insulin resistance, and obesity strengthening the belief of a common genetic linkage.

- These people tend to have more arterial abnormalities than the rest of the patients who had MI < 45 years.
Parental history of MI is associated with a two-fold greater risk of CAC in Caucasians (95% CI = 1.38–2.92).
I. ATHEROMATOUS CAD

Lipid abnormalities

- Especially hypertriglyceridaemia and low HDL were found to be more common in patients who had their MI <45 years. Apart from overt diabetes, impaired glucose tolerance was found in 65% of young survivors after MI.
Nonoptimal Lipids Commonly Present in Young Adults and Coronary Calcium Later in Life: The CARDIA (Coronary Artery Risk Development in Young Adults) Study

Mark J. Fletcher, MD, MPH; Kirsten Bibbins-Domingo, PhD, MD; Kiang Liu, PhD; Steve Sidney, MD, MPH; Feng Lin, MS; Eric Vittinghoff, PhD; and Stephen B. Hulley, MD, MPH

Background: Dyslipidemia causes coronary heart disease in middle-aged and elderly adults, but the consequences of lipid exposure during young adulthood are unclear.

Objective: To assess whether nonoptimal lipid levels during young adulthood cause atherosclerotic changes that persist into middle age.

Design: Prospective cohort study.

Setting: 4 cities in the United States.

Participants: 3,258 participants from the 5,115 black and white men and women recruited at age 18 to 30 years in 1985 to 1986 for the CARDIA (Coronary Artery Risk Development in Young Adults) study.

Measurements: Low-density lipoprotein (LDL) and high-density lipoprotein (HDL) cholesterol, triglycerides, and coronary calcium. Time-averaged cumulative exposures to lipids between age 20 and 35 years were estimated by using repeated serum lipid measurements over 20 years in the CARDIA study; these measurements were then related to coronary calcium scores assessed later in life (45 years [SD, 4]).

Results: 2,824 participants (87%) had nonoptimal levels of LDL cholesterol (≥2.59 mmol/L [≥100 mg/dL]), HDL cholesterol (<1.55 mmol/L [<60 mg/dL]), or triglycerides (≥1.70 mmol/L [≥150 mg/dL]) during young adulthood. Coronary calcium prevalence 2 decades later was 8% in participants who maintained optimal LDL levels (<1.81 mmol/L [<70 mg/dL]), and 44% in participants with LDL cholesterol levels of 4.14 mmol/L (160 mg/dL) or greater (P < 0.001). The association was similar across race and sex and strongly graded, with odds ratios for coronary calcium of 1.5 (95% CI, 0.7 to 3.3) for LDL cholesterol levels of 1.81 to 2.56 mmol/L (70 to 99 mg/dL), 2.4 (CI, 1.1 to 5.3) for levels of 2.59 to 3.34 mmol/L (100 to 129 mg/dL), 3.3 (CI, 1.3 to 7.8) for levels of 3.37 to 4.12 mmol/L (130 to 159 mg/dL), and 5.6 (CI, 2.0 to 16) for levels of 4.14 mmol/L (160 mg/dL) or greater, compared with levels less than 1.81 mmol/L (<70 mg/dL), after adjustment for lipid exposure after age 35 years and other coronary risk factors. Both LDL and HDL cholesterol levels were independently associated with coronary calcium after participants who were receiving lipid-lowering medications or had clinically abnormal lipid levels were excluded.

Limitation: Coronary calcium, although a strong predictor of future coronary heart disease, is not a clinical outcome.

Conclusion: Nonoptimal levels of LDL and HDL cholesterol during young adulthood are independently associated with coronary atherosclerosis 2 decades later.

Primary Funding Source: National Heart, Lung, and Blood Institute.

For author affiliations, see end of text.
Nonoptimal levels of LDL chol. (>100mg/dL), HDL chol. (<60 mg/dL), or triglycerides ≥150mg/dL were found in 87% of young adults in the study.

I. ATHEROMATOUS CAD

Novel risk factors

- Conventional risk factors play a larger part in younger patients who had MI.

- Emergence of novel risk factors for CHD like hyperhomocysteinaemia and lipoprotein (a) among adults of different age group may have the same clinical implications in younger people.

- Premature CHD is a rapidly progressive form of atheromatous process.

- Entirely unexplored areas like anger and psychosocial stress can add a significant morbidity and were associated with MI and coronary artery calcification in young adults.
Ομοκυστεΐνη

- Φυσιολογικά κυμαίνονται από 5-15 μmol/l

Σχέση ομοκυστεΐνης και αθηροθρομβωτικής διεργασίας

1) Δυσλειτουργία ενδοθηλίου μέσω ελάττωσης της παραγωγής του ΝΟ
2) Ευόδωση θρόμβωσης ενεργοποιώντας τα αιμοπετάλια και επίσης επάγοντας την παραγωγή του ιστικού παράγοντα
3) Επιτάχυνση οξείδωσης της LDL
4) Αύξηση οξειδωτικού stress

22% νεαρών εμφραγματιών έχει επίπεδα ομοκυστεΐνης >15 μmol/l [Ραλλιδης 2009]
II. NON-ATHEROMATOUS CAD
Congenital Coronary Abnormalities

• Can present for the first time as MI in young adults. rare and may be a surprise to the cardiologist

• **Myocardial bridging**, been reported in young people presenting with MI. can result in significant ischaemia during systolic contraction and can result in MI.

• PCI and surgical splitting were found to be more useful than medical management in this group of patients.
II. NON-ATHEROMATOUS CORONARY ABNORMALITIES

- **Coronary artery dissection** can occur spontaneously in young adults. The chest pain is often *atypical* and women are at a higher risk during their **peripartum period**.
- **LAD** was found to be the culprit artery in most of the cases.
- Unfortunately the diagnosis is often made at necropsy. Successful treatment with stenting or surgery has been reported.
II. NON-ATHEROMATOUS CORONARY ABNORMALITIES

- **Septic vegetation** from infected aortic valve was reported to have caused MI in younger people. Intravenous drug misusers are at a higher risk.

- MI has been reported to occur as a result of *bacteraemia* in the absence of vegetations in young people. Management entails treatment of the underlying source of sepsis as well.

- **Coronary artery aneurysms**: rare cause of MI in younger adults the mechanism either attributable to embolisation from the aneurysmal sac or extra luminal compression.

- **Paradoxical embolisation** from right to left, through a patent foramen ovale, leading to MI has also been reported.
III. RECREATIONAL DRUG USE

- The diagnostic challenge in confirming MI is complicated by the increased prevalence of false positive creatinine kinase rise. Serious arrhythmias including ventricular tachycardia can occur in cocaine users in the absence of MI. Apart from MI, cocaine use has been associated with cardiomyopathy, tachyarrhythmias, and endocarditis.

- Amphetamine and marihuana use can result in MI but the data are limited. Binge drinking of alcohol has also been reported to be associated with developing MI in a young person, although the mechanism is not entirely clear.
III. RECREATIONAL DRUG USE

- **Cocaine** use is associated with various cardiac complications including MI. Among young patients admitted with non-traumatic chest pain in the ER, cocaine use was found to associate with the clinical presentation in 48%.

- A detailed history is vital as cocaine effects can present **up to 76 hours after its use**. Most of the patients who misuse cocaine are also found to be smokers and this makes them more vulnerable for MI.
III. RECREATIONAL DRUG USE

• MI was diagnosed, based on an increase in cardiac troponins, in 6% of the people admitted to the emergency department after various complications after cocaine use.

• Cocaine use results in acute MI by various mechanisms including coronary vasospasm and hypercoagulability in the background of heightened sympathetic activity. Long term cocaine use also results in hastened atherosclerosis.
ACS AND COCAINE USE:

Annual Prevalence according to patient history and urine test

Carirllo X. Eur. Heart Journal; 2011, 32
ACS AND COCAINE USE

Prevalence according to pt history and urine test by age group.
VI. HYPERCOAGULABLE STATES

• Nephrotic syndrome is associated with hypercoagulability attributable to the combination of various factors like disturbances of the fibrinolytic system, dyslipidaemia, and a decrease in anticoagulant factors. Reduction in concentration of antithrombin III, a coagulation inhibitor was particularly responsible for the thrombophilic tendency in most of the subjects.

• Factor V Leiden mutation is associated with a procoagulant state and has been reported to result in MI in young people; smokers are particularly at higher risk. Contraceptive pill use increases the risk of developing MI in young women because of its procoagulant activity.

Παράγων V Leiden δεν συνδέεται πρώιμο EM

Πολυμορφισμός G20210A της προθρομβίνης;
IV. HYPERCOAGULABLE STATES

• **Antiphospholipid syndrome** is associated with recurrent arterial and venous thrombosis. It is often the disease of the young in their 30s. It can be primary or secondary associated with other autoimmune diseases like systemic lupus erythematosus.

• Thrombotic occlusion of a coronary artery can result in acute MI. These patients tend to have premature **atherosclerosis and increased platelet adhesiveness**.

• The titres of antiphospholipid antibodies need not be associated with disease activity and detailed evaluation is recommended to arrive at a diagnosis in suspected people.
Αντιφωσφολιπιδικό σύνδρομο

1) Αυτοάνοσο νόσημα που συνδέεται με αγγειακές θρομβώσεις και αυξημένη νοσηρότητα κατά την εγκυμοσύνη

2) Θέσεις αρτηριακών θρομβώσεων (εγκεφαλικές >στεφανιαίες αρτ)

Διαγνωστικά κριτήρια (οριστική ≥1 κλινικό + ≥1 εργαστηριακό)

Κλινικά:
- Αγγειακές θρομβώσεις: αρτηριακές, φλεβικές ή μικρών αγγείων
- Αυξημένη νοσηρότητα κατά την εγκυμοσύνη: απώλεια ≥1 εμβρύων < ή >10η εβδομάδα, πρόωρος τοκετός <34η εβδομάδα συνεπεία εκλαμψίας ή σοβαρής προεκλαμψίας, ≥3 αυτόματες αποβολές <10η εβδομάδα εγκυμοσύνης

Εργαστηριακά (τουλάχιστον 2 προσδιορισμοί, απόσταση ≥3 μηνών):
- Αντιπηκτικό του λύκου
- Αντισώματα κατά καρδιολιπίνης (IgG και/ή IgM) [>40 U]
- Αντισώματα κατά αντι-β₂-γλυκοπρωτεϊνης I (IgG και IgM)

CONCLUSION

- Although MI, fortunately, is an uncommon entity in young adults, it constitutes an **important problem** for both the patient and the treating physician.

- It has a devastating effect on the more active lifestyle of young patients.

- These young patients also have a **different risk factor** profile, clinical presentation, and prognosis in comparison with older patients, which has to be taken into consideration when treating these young adults presenting with MI. **The increased prevalence of risk factors for CHD may set up an alarming trend.**
CONCLUSION

• Substance misuse, coronary artery anomalies, premature coronary artery disease, and hypercoagulable state have to be considered in all young patients with suspected MI.

• Early stabilisation should be followed by risk stratification, and early revascularisation, where appropriate, should be offered as it carries a better clinical outcome. Risk factors modification should be emphasised.

• It is strongly emphasised the importance of secondary preventive measures in all young patients admitted with ACS as the long term mortality can reach up to one third if not treated appropriately.
CLINICAL PRESENTATION OF MI IN THE YOUNG PATIENT,

**Clues**

- In every young with MI, use of recreational drugs in the recent times should be recorded. Family history of premature CHD, risk factor profile such as smoking, obesity, diabetes, and dyslipidaemia would give better clues as to the likelihood of atheromatous coronary artery disease.

- History of recurrent venous and arterial thrombosis should also be reported.
ΣΥΓΚΡΙΣΗ PDAY SCORE KAI FRS

• Στην Framingham Heart Study στον πληθυσμό μελέτης δεν υπήρχαν < 30 ετών.
• Στο Framingham risk score υπάρχουν αρνητικές τιμές για ηλικίες <30 ετών.
• Το PDAY risk score προβλέπει αθηρογένεση.
• Το Framingham risk score προβλέπει κίνδυνο για κλινικά συμβάματα από στεφανιαία νόσο.
We included 10,551 male participants of the CHA in Chicago Heart Association Study who were aged 18 to 39 years and free of baseline CHD and diabetes at enrollment from 1967 to 1973. Risk of CHD was estimated using both FRS and ATP III online risk estimator for each individual. In conclusion, both the FRS and the ATP III online risk estimator were able to order risk. The FRS was unable to classify the young adults in this cohort as anything other than low risk even in the face of a substantial risk factor burden estimates accurately among young adult men. However, neither strategy was able to identify high risk individuals (i.e. >20% absolute risk in 10 years) younger than 30 years despite substantial risk factor burden. Future clinical guidelines should consider alternative strategies to estimate and communicate CVD risk to the young adult population.
The risk score computed from risk factors measured 10 to 15 years before the assessment of CAC performed better than the risk score computed from risk factors at the time of CAC assessment. If the risk score increased between year 0 and year 15, the likelihood of developing CAC increased; if the risk score decreased, the likelihood of developing CAC decreased. The PDAY risk score and a revised PDAY risk score that included family history of cardiovascular disease and a greater differential between the sexes performed better than the Framingham risk score.
Results from stepwise conditional logistic regression analysis that evaluated participants’ characteristics on the odds of having acute myocardial infarction

* Η παρουσία του γονότυπου TT συνδέεται με 3,4 φορές μεγαλύτερο κίνδυνο (p=0,03) για ανάπτυξη πρώιμου ΕΜ με «φυσιολογικά» στεφανιαία αγγεία

* Συμπερασματικά
  Η ομοζυγωτικές του πολυμορφισμού της MTHFR 677C->T φαίνεται να ευνοεί την ανάπτυξη ΕΜ σε άτομα που έχουν μικρό αθηρωματικό φορτίο
II. NON-ATHEROMATOUS CORONARY ABNORMALITIES

• **Coronary artery dissection** can occur spontaneously in young adults. The chest pain is often atypical and women are at a higher risk during their peripartum period.

• **LAD** was found to be the culprit artery in most of the cases. Unfortunately the diagnosis is often made at necropsy. Successful treatment with stenting or surgery has been reported.
The incidence of CHD is declining in all age groups. The actual prevalence is 0.5% in men and 0.18% in women aged 35 - 44 years, 20.5% in men, and 17.1% in women > 60 years.

In fact, the figures in young patients may be lower than actual because of atypical presentation and reluctance to submit themselves for further investigations.

However, CHD in younger population <40 years represents only 3% of all patients with CHD.
